**Substituted Pyridines Useful for Inhibiting  
Cholesteryl Ester Transfer Protein Activity**

**Field of the Invention**

This invention is in the field of preventing and/or  
5 treating cardiovascular disease, and specifically relates  
to compounds, compositions and methods for preventing  
and/or treating atherosclerosis and other coronary artery  
disease. More particularly, the invention relates to  
substituted pyridine compounds that inhibit cholesteryl  
10 ester transfer protein (CETP), also known as plasma lipid  
transfer protein-I.

**Background of the Invention**

Numerous studies have demonstrated that a low plasma  
concentration of high density lipoprotein (HDL)  
15 cholesterol is a powerful risk factor for the development  
of atherosclerosis (Barter and Rye, *Atherosclerosis*, 121,  
1-12 (1996)). HDL is one of the major classes of  
lipoproteins that function in the transport of lipids  
through the blood. The major lipids found associated  
20 with HDL include cholesterol, cholesteryl ester,  
triglycerides, phospholipids and fatty acids. The other  
classes of lipoproteins found in the blood are low  
density lipoprotein (LDL) and very low density  
lipoprotein (VLDL). Since low levels of HDL cholesterol  
25 increase the risk of atherosclerosis, methods for  
elevating plasma HDL cholesterol would be therapeutically  
beneficial for the treatment of atherosclerosis and other  
diseases associated with accumulation of lipid in the  
blood vessels. These diseases include, but are not  
30 limited to, coronary heart disease, peripheral vascular  
disease, and stroke.

Atherosclerosis underlies most coronary artery  
disease (CAD), a major cause of morbidity and mortality  
in modern society. High LDL cholesterol (above 180

mg/dl) and low HDL cholesterol (below 35 mg/dl) have been shown to be important contributors to the development of atherosclerosis. Other diseases, such as peripheral vascular disease, stroke, and hypercholesterolaemia are 5 negatively affected by adverse HDL/LDL ratios.

Inhibition of CETP by the subject compounds are shown to effectively modify plasma HDL/LDL ratios, and to check the progress and/or formation of these diseases.

CETP is a plasma protein that facilitates the 10 movement of cholesteryl esters and triglycerides between the various lipoproteins in the blood (Tall, *J. Lipid Res.*, 34, 1255-74 (1993)). The movement of cholesteryl ester from HDL to LDL by CETP has the effect of lowering HDL cholesterol. It therefore follows that inhibition of 15 CETP should lead to elevation of plasma HDL cholesterol and lowering of plasma LDL cholesterol, thereby providing a therapeutically beneficial plasma lipid profile (McCarthy, *Medicinal Res. Revs.*, 13, 139-59 (1993)). This exact phenomenon was first demonstrated by Swenson 20 et al., (*J. Biol. Chem.*, 264, 14318 (1989)) with the use of a monoclonal antibody that specifically inhibited CETP. In rabbits, the antibody caused an elevation of the plasma HDL cholesterol and a decrease in LDL cholesterol. Son et al. (*Biochim. Biophys. Acta* 795, 25 743-480 (1984)) describes proteins from human plasma that inhibit CETP. U.S. Patent 5,519,001, issued to Kushwaha et al., describes a 36 amino acid peptide derived from baboon apo C-1 that inhibits CETP activity.

There have been several reports of compounds that 30 act as CETP inhibitors. Barrett et al. (*J. Am. Chem. Soc.*, 118, 7863-63 (1996)) describes cyclopropane-containing CETP inhibitors. Pietzonka et al. (*Bioorg. Med. Chem. Lett.*, 6, 1951-54 (1996)) describe phosphonate-containing analogs of cholesteryl ester as 35 CETP inhibitors. Coval et al. (*Bioorg. Med. Chem. Lett.*, 5, 605-610 (1995)) describe Wiedendiol-A and -B, and

related sesquiterpene compounds, as CETP inhibitors. Lee et al. (*J. Antibiotics*, 49, 693-96 (1996)) describe CETP inhibitors derived from an insect fungus. Busch et al. (*Lipids*, 25, 216-220, (1990)) describe cholesteryl acetyl bromide as a CETP inhibitor. Morton and Zilversmit (*J. Lipid Res.*, 35, 836-47 (1982)) describe that p-chloromercuriphenyl sulfonate, p-hydroxymercuribenzoate and ethyl mercurithiosalicylate inhibit CETP. Bisgaier et al. (*Lipids*, 29, 811-8 (1994) describe 4-phenyl-5-tridecyl-4H-1,2,4-triazole-thiol as a CETP inhibitor.

A number of substituted pyridine compounds are known. For example, U.S. Patents 4,609,399, 4,655,816; 4,692,184; 4,698,093; 4,789,395; 4,885,026; 4,936,905; 4,988,384; 5,037,469; 5,125,961; 5,129,943; 5,156,670; 5,169,432; and 5,260,262 each disclose novel substituted pyridines which are useful as herbicides and herbicide intermediates. No pharmacologic properties for the substituted pyridines are recited in these patents. Except as set forth below, the literature does not describe substituted pyridines as inhibitors of CETP.

Connolly et al. (*Biochem. Biophys. Res. Comm.* 223, 42-47 (1996)), describe 4,4'-dithiopyridine, 2,2'-dithiopyridine, 6,6'-dithionicotinic acid and 2,2'-dithiobis (pyridine-N-oxide) as CTEP inhibitors. The isolated pyridine compounds tested by Connolly et al. were, at best, inhibitory only after a 16 hour pre-incubation period and would not be useful in situations requiring rapid and potent inhibition. Connolly et al. also neither addressed whether substitution of the reported pyridines would increase their potency nor suggested the testing or use of specific substituted pyridines.

European Patent Application 796 846 A1 describes certain 2-aryl-substituted pyridines for use in the treatment of lipoproteinaemia and hyperlipoproteinaemia.

European Patent Application 818 197 A1 describes

certain 2-aryl-substituted pyridines for use in the treatment of hyperlipoproteinaemia and atherosclerosis.

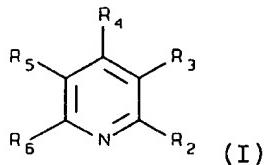

U.S. Patent 4,925,852 describes 3-demethylmevalonic acid derivatives for use as inhibitors of cholesterol biosynthesis.

U.S. Patent 5,169,857 describes 7-(polysubstituted pyridyl)-hept-6-endates for use in the treatment of hyperproteinaemia, lipoproteinaemia or arteriosclerosis.

WO 98/04528 describes certain 4-aryl-pyridyl compounds as anti-hypercholesterolemic, anti-hyperlipoproteinemic and anti-hyperglycemic agents.

#### Pharmaceutically Acceptable Salts

Also included in the family of compounds of Formulae I, IA and IB used in the method of the present invention (as well as in the family of novel compounds of Formula 25 IIA and IIB discussed below) are the pharmaceutically-acceptable salts thereof. The term "pharmaceutically-acceptable salts" embraces salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. The nature 30 of the salt is not critical, provided that it is pharmaceutically acceptable. Suitable pharmaceutically-acceptable acid addition salts may be prepared from an inorganic acid or from an organic acid. Examples of such inorganic acids are hydrochloric, hydrobromic,

hydroiodic, nitric, carbonic, sulfuric and phosphoric acid. Appropriate organic acids may be selected from aliphatic, cycloaliphatic, aromatic, araliphatic, heterocyclic, carboxylic and sulfonic classes of organic acids, examples of which are formic, acetic, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, ascorbic, glucoronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic, anthranilic, mesylic, salicylic, p-hydroxybenzoic, phenylacetic, mandelic, 10 embonic (pamoic), methanesulfonic, ethylsulfonic, benzenesulfonic, sulfanilic, stearic, cyclohexylaminosulfonic, algenic, galacturonic acid.. Suitable pharmaceutically-acceptable base addition salts include metallic salts made from aluminum, calcium, 15 lithium, magnesium, potassium, sodium and zinc or organic salts made from N,N'-dibenzylethylenediamine, choline, chloroprocaine, diethanolamine, ethylenediamine, meglumine (N-methylglucamine) and procain. All of these salts may be prepared by conventional means from the 20 corresponding compound by reacting, for example, the appropriate acid or base with the compound.

**Treatment of CETP-Mediated Disorders**

The methods of this invention additionally can be used, for example: (i) to inhibit cholesteryl ester transfer protein (CETP) activity, (ii) to decrease the concentrations of low density lipoprotein (LDL) and/or raise the level of high density lipoprotein (HDL), or otherwise alter lipoprotein profiles, resulting in a therapeutically beneficial plasma lipid profile; (iii) for the primary and secondary treatment of coronary artery disease, myocardial infarction and agina; (iv) for the treatment of dyslipidemia (hypoalphalipoproteinaemia), hyperlipoproteinaemia (chylomicronemia and hyperapobetalipoproteinaemia), 35 peripheral vascular disease, hypercholesterolemia,

atherosclerosis, and other CETP-mediated disorders; (v) for the prophylactic treatment of subjects who are at risk of developing CETP-mediated disorders; and (vi) to lower the risk of atherosclerosis. The methods would be 5 also useful in prevention of cerebral vascular accident (CVA) or stroke.

Besides being useful for human treatment, these methods are also useful for veterinary treatment of companion animals, exotic animals and farm animals, 10 including mammals, rodents, and the like. More preferred animals include horses, dogs, and cats.

Without being limited to a specific theory, applicant hypothesizes that the CETP molecule contains one or more specific hydrophobic binding sites that can 15 accommodate the substituted pyridines of the present invention. Binding of the substituted pyridine to these sites is sufficient to inhibit CETP. This binding is generally rapid and reversible.

It is additionally hypothesized that the CETP 20 molecule contains a cysteine at or near these hydrophobic binding sites. Inhibition potency can be enhanced by selecting a substituted pyridine which is capable of undergoing a disulfide exchange with this cysteine. This disulfide exchange is time-dependent and irreversible. 25 While inhibition potency may be enhanced as a result of this disulfide exchange, substituted pyridines which are effective inhibitors and which do not undergo the disulfide exchange may be more desirable given the generally irreversible nature of the disulfide exchange 30 reaction.

It is further hypothesized that such disulfide-modified CETP molecules can aggregate, perhaps as a result of conformational changes induced by interaction with the substituted pyridine.

Pharmaceutical Compositions

Also embraced within this invention is a class of pharmaceutical compositions comprising the active compounds of Formulae I, IA, IB and/or Formulae IIA or 5 IIB in association with one or more non-toxic, pharmaceutically-acceptable carriers and/or diluents and/or adjuvants (collectively referred to herein as "carrier" materials) and, if desired, other active ingredients. The active compounds of the present 10 invention may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The active compounds and compositions may, for example, be administered orally, 15 intravascularly, intraperitoneally, subcutaneously, intramuscularly or topically.

The phrase "co-therapy" (or combination-therapy), in defining use of a compound of the present invention and another pharmaceutical agent, is intended to embrace 20 administration of each agent in a sequential manner in a regimen that will provide beneficial effects of the drug combination, and is intended as well to embrace co-administration of these agents in a substantially simultaneous manner, such as in a single capsule having a 25 fixed ratio of these active agents or in multiple, separate capsules for each agent. The compounds of the invention can be administered as the sole active pharmaceutical agent, they can also be used in co-therapy with one or more cardiovascular agents, such as compounds 30 that lower serum cholesterol concentrations including inhibitors of cholesterol biosynthesis such as HMG-CoA reductase inhibitors such as the statins (atorvastatin, cerivastatin, pravastatin, simvastatin, fluvastatin and lovastatin), inhibitors of squalene synthase, oxido 35 squalene cyclase or inhibitors of other enzymes involved with cholesterol biosynthesis; inhibitors of the ileal

bile acid transport protein (IBAT), cholesterol absorption antagonists, ACAT inhibitors, bile acid sequestrants such as Cholestyramine and Cholestagel, fibrates such as Gemfibrozil, niacins such as Niaspan, 5 and omega-3 fatty acids such as Omacor. Compounds of the present invention can also be used in co-therapy with cardiovascular drugs that reduce hypertension such as Enalopril and Captopril, or with anti-diabetes drugs such as troglitazone, or with antithrombotic agents such as 10 aspirin, warfarin, and glycoprotein IIbIIIa antagonists such as Reopro, Xemilofiban and Orbofiban. The compounds of this invention can also be used in co-therapy with agents which lower serum triglyceride concentrations, including inhibitors of cholesterol biosynthesis such as 15 HMG-CoA reductase inhibitors such as the statins (atorvastatin), fibrates such as Gemfibrozil, niacins such as Niaspan, and omega-3 fatty acids such as Omacor.

The phrase "therapeutically-effective" is intended to qualify the amount of each agent which will achieve 20 the goal of improvement in disease severity and the frequency of incidence over treatment of each agent by itself, while avoiding adverse side effects typically associated with alternative therapies.

For oral administration, the pharmaceutical 25 composition may be in the form of, for example, a tablet, capsule, suspension or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. Examples of such dosage units are tablets or 30 capsules. The active ingredient may also be administered by injection as a composition wherein, for example, saline, dextrose or water may be used as a suitable carrier.

The amount of therapeutically active compounds which 35 are administered and the dosage regimen for treating a disease condition with the compounds and/or compositions

of this invention depends on a variety of factors, including the age, weight, sex and medical condition of the subject, the severity of the disease, the route and frequency of administration, and the particular compound 5 employed, and thus may vary widely. Patients undergoing treatment with the compounds and/or compositions disclosed herein can be routinely monitored by conventional methods to determine the effectiveness of therapy. Continuous analysis of the data obtained 10 permits modification of the treatment regimen during treatment so that optimal amounts of the compounds and/or compositions of this invention are administered, and so that the duration of treatment can be determined as well. Thus, the treatment regimen/dosing schedule can be 15 rationally modified over the course of treatment so as to achieve the lowest doses of each of the compounds and/or compositions of this invention which together result in satisfactory anti-lipidemic effectiveness, and so that administration of these compounds is continued only so 20 long as is necessary to successfully treat the patient.

The pharmaceutical compositions may contain active ingredients in the range of about 0.1 to 2000 mg, and preferably in the range of about 0.5 to 500 mg. A daily dose of about 0.01 to 100 mg/kg body weight, and 25 preferably between about 0.5 and about 20 mg/kg body weight, may be appropriate. The daily dose can be administered in one to four doses per day.

The compounds may be formulated in topical ointment or cream, or as a suppository, containing the active 30 ingredients in a total amount of, for example, 0.075 to 30% w/w, preferably 0.2 to 20% w/w and most preferably 0.4 to 15% w/w. When formulated in an ointment, the active ingredients may be employed with either paraffinic or a water-miscible ointment base. Alternatively, the 35 active ingredients may be formulated in a cream with an oil-in-water cream base. If desired, the aqueous phase

of the cream base may include, for example at least 30% w/w of a polyhydric alcohol such as propylene glycol, butane-1,3-diol, mannitol, sorbitol, glycerol, polyethylene glycol and mixtures thereof. The topical 5 formulation may desirably include a compound which enhances absorption or penetration of the active ingredient through the skin or other affected areas. Examples of such dermal penetration enhancers include dimethylsulfoxide and related analogs. The compounds of 10 this invention can also be administered by a transdermal device. Preferably topical administration will be accomplished using a patch either of the reservoir and porous membrane type or of a solid matrix variety. In either case, the active agent is delivered continuously 15 from the reservoir or microcapsules through a membrane into the active agent permeable adhesive, which is in contact with the skin or mucosa of the recipient. If the active agent is absorbed through the skin, a controlled and predetermined flow of the active agent is 20 administered to the recipient. In the case of microcapsules, the encapsulating agent may also function as the membrane.

The oily phase of the emulsions of this invention 25 may be constituted from known ingredients in a known manner. While the phase may comprise merely an emulsifier, it may comprise a mixture of at least one emulsifier with a fat or an oil or with both a fat and an oil. Preferably, a hydrophilic emulsifier is included together with a lipophilic emulsifier which acts as a 30 stabilizer. It is also preferred to include both an oil and a fat. Together, the emulsifier(s) with or without stabilizer(s) make-up the so-called emulsifying wax, and the wax together with the oil and fat make up the so-called emulsifying ointment base which forms the oily 35 dispersed phase of the cream formulations. Emulsifiers and emulsion stabilizers suitable for use in the

formulation of the present invention include Tween 60, Span 80, cetostearyl alcohol, myristyl alcohol, glyceryl monostearate, and sodium lauryl sulfate, among others.

The choice of suitable oils or fats for the formulation is based on achieving the desired cosmetic properties, since the solubility of the active compound in most oils likely to be used in pharmaceutical emulsion formulations is very low. Thus, the cream should preferably be a non-greasy, non-staining and washable product with suitable consistency to avoid leakage from tubes or other containers. Straight or branched chain, mono- or dibasic alkyl esters such as di-isoadipate, isocetyl stearate, propylene glycol diester of coconut fatty acids, isopropyl myristate, decyl oleate, isopropyl palmitate, butyl stearate, 2-ethylhexyl palmitate or a blend of branched chain esters may be used. These may be used alone or in combination depending on the properties required. Alternatively, high melting point lipids such as white soft paraffin and/or liquid paraffin or other mineral oils can be used.

Formulations suitable for topical administration to the eye also include eye drops wherein the active ingredients are dissolved or suspended in suitable carrier, especially an aqueous solvent for the active ingredients. The antiinflammatory active ingredients are preferably present in such formulations in a concentration of 0.5 to 20%, advantageously 0.5 to 10% and particularly about 1.5% w/w.

For therapeutic purposes, the active compounds of this combination invention are ordinarily combined with one or more adjuvants appropriate to the indicated route of administration. If administered per os, the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric

and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and then tableted or encapsulated for convenient administration. Such capsules or tablets may contain a controlled-release formulation as may be provided in a dispersion of active compound in hydroxypropylmethyl cellulose. Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules having one or more of the carriers or diluents mentioned for use in the formulations for oral administration. The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art.

20     Additional Substituted Pyridines

The present invention further includes a group of substituted pyridines which exhibit percentage transfers in excess of 100% and are useful (i) in examining the structural requirements of the active site of the CETP molecule, (ii) as control pyridines in the study of the mechanism for inhibiting the activity of CETP, and (iii) in the design of substituted pyridines which are effective CETP inhibitors. Accordingly, they are useful in studying the prevention and treatment of dyslipidemia (hypoalphalipoproteinaemia), hyperlipoproteinaemia (chylomicronemia and hyperapobetalipoproteinaemia), peripheral vascular disease, hypercholesterolemia, atherosclerosis, coronary artery disease and other CETP-mediated disorders. These substituted pyridines include those compounds listed in Table 13 below:

Biological Activity ExamplesExample 54**CETP Activity In Vitro**

The ability of compounds to inhibit CETP were assessed using an *in vitro* assay that measured the rate of transfer of radiolabeled cholesteryl ester ( $[^3H]CE$ ) from HDL donor particles to LDL acceptor particles. Details of the assay are provided by Glenn et al. ("Quantification of Cholesteryl Ester Transfer Protein (CETP): A) CETP Activity and B) Immunochemical Assay of CETP Protein," *Meth. Enzymol.*, Glenn and Melton (Meth. Enzymol., 263, 339-351 (1996), which is incorporated herein by reference). CETP was obtained from the serum-free conditioned medium of CHO cells transfected with a cDNA for CETP (Wang, S. et al. *J. Biol. Chem.* 267, 17487-17490 (1992), which is incorporated herein by

reference).

To measure CETP activity, [<sup>3</sup>H]CE-labeled HDL, LDL, CETP and assay buffer (50 mM tris(hydroxymethyl)amino-methane, pH 7.4; 150 mM sodium chloride; 2 mM ethylenediamine-tetraacetic acid; 1% bovine serum albumin) were incubated in a volume of 200 µl, for 2 hours at 37°C in 96 well plates. LDL was differentially precipitated by the addition of 50 µl of 1% (w/v) dextran sulfate/0.5 M magnesium chloride, mixed by vortex, and incubated at room temperature for 10 minutes. The solution (200µl) was transferred to a filter plate (Millipore). After filtration, the radioactivity present in the precipitated LDL was measured by liquid scintillation counting. Correction for non-specific transfer or precipitation was made by including samples that did not contain CETP. The rate of [<sup>3</sup>H]CE transfer using this assay was linear with respect to time and CETP concentration, up to 25-30% of [<sup>3</sup>H]CE transferred.

The potency of test compounds was determined by performing the above described assay in the presence of varying concentrations of the test compounds and determining the concentration required for 50% inhibition of transfer of [<sup>3</sup>H]CE from HDL to LDL. This value was defined as the IC<sub>50</sub>. The IC<sub>50</sub> values determined by this method for the substituted pyridine compounds of the invention are specified in **Tables 1-8**.

#### Example 55

##### **Whole Serum CETP Activity Assay (Tritiated Cholesterol Ester)**

Blood was obtained from healthy volunteers recruited from the personnel of Monsanto Company, Saint Louis, MO. Blood was either collected in tubes containing EDTA (EDTA plasma pool) or in tubes without EDTA (spun to form the serum pool). The EDTA human plasma pool or human serum pool, previously stored at -20°C, was thawed at room

temperature, and centrifuged for 5 minutes to remove any particulate matter. Tritiated HDL, radiolabeled in the cholestryl ester moiety ( $[^3\text{H}]$ CE-HDL) as described by Morton and Zilversmit (J. Biol. Chem., 256, 11992-95  
5 (1981) which is incorporated by reference herein), was added to the plasma or serum to a final concentration of (25  $\mu\text{g}/\text{ml}$  cholesterol).

Inhibitor compounds were added to the plasma or serum as follows: Equal volumes of the plasma or serum  
10 containing the  $[^3\text{H}]$ CE-HDL (396  $\mu\text{l}$ ) were pipetted into micro tubes (Titertube<sup>®</sup>, Bio-Rad Laboratories, Hercules, CA). Compounds, usually dissolved as 20-50 mM stock solutions in DMSO, were serially diluted in DMSO (or an alternative solvent in some cases, such as  
15 dimethylformamide or ethanol). Four  $\mu\text{l}$  of each of the serial dilutions of inhibitor compounds or DMSO alone were then added to each of the plasma or serum tubes. The tubes were immediately mixed. Triplicate aliquots (100  $\mu\text{l}$ ) from each plasma or serum tube were then  
20 transferred to wells of 96-well round-bottomed polystyrene microtiter plates (Corning, Corning, NY). Plates were sealed with plastic film and incubated at 37 °C for 4 hours.

Test wells contained plasma or serum with dilutions  
25 of inhibitor compounds. Control wells contained plasma or serum with DMSO alone. Blank wells contained plasma or serum with DMSO alone that were left in the micro tubes at 4°C for the 4 hour incubation and were added to the microtiter wells at the end of the incubation period.  
30 VLDL and LDL were precipitated by the addition of 10  $\mu\text{l}$  of precipitating reagent (1% (w/v) Dextran Sulfate (Dextralip50)/0.5M magnesium chloride, pH 7.4) to all wells. The wells were mixed on a plate mixer and then incubated at ambient temperature for 10 min. The plates  
35 were then centrifuged at 1000 x g for 30 mins at 10°C. The supernatants (50  $\mu\text{l}$ ) from each well were then

transferred to Picoplate™ 96 plate wells (Packard, Meriden, CT) containing 250:1 Microscint™-40 (Packard, Meriden, CT). The plates were heat-sealed (TopSeal™-P, Packard, Meriden, CT) according to the manufacturers directions and mixed for 30 min.

5 Radioactivity was measured on a microplate scintillation counter (TopCount, Packard, Meriden, CT). IC<sub>50</sub>'s were determined as the concentration of inhibitor compound inhibiting transfer of [<sup>3</sup>H]CE from the supernatant [<sup>3</sup>H]CE-HDL to the precipitated VLDL and LDL by 50% compared to the transfer obtained in the control wells. The maximum percent transfer (in the control wells) was determined using the following equation:

10

$$\text{% Transfer} = \frac{[\text{dpm}_{\text{blank}} - \text{dpm}_{\text{control}}] \times 100}{\text{dpm}_{\text{blank}}}$$

15 The percent of control transfer determined in the wells containing inhibitor compounds was determined as follows:

$$20 \text{ % Control} = \frac{[\text{dpm}_{\text{blank}} - \text{dpm}_{\text{test}}] \times 100}{\text{dpm}_{\text{blank}} - \text{dpm}_{\text{control}}}$$

25 IC<sub>50</sub> values were then calculated from plots of % control versus concentration of inhibitor compound. The IC<sub>50</sub> values of the substituted pyridine compounds determined by this method are as follows: Compound 7, 17 micromolar; Compound 180, 9 micromolar; Compound 181, 16 micromolar; Compound 214, 70 micromolar; and Compound 35 215, 110 micromolar.

Example 56**Inhibition of CETP Activity In Vivo**

Inhibition of CETP by a test compound can be determined by administering the compound to an animal by 5 intravenous injection, determining the rate of transfer of tritium-labeled cholesteryl ester ( $^3\text{H}$ ]CE) from HDL to VLDL and LDL particles, and comparing the rate of transfer with the rate of transfer observed in control animals.

10 Male golden Syrian hamsters were maintained on a diet of chow containing 0.24% cholesterol for at least two weeks prior to the study. Immediately before the experiment, animals were anesthetized with pentobarbital. Anesthesia was maintained throughout the experiment.

15 Indwelling catheters were inserted into the jugular vein and carotid artery. Test compound, Dimethyl 5,5'-dithiobis[2-difluoromethyl]-4-(2-methylpropyl)-6-(trifluoromethyl)-3-pyridinecarboxylate] (Compound 181), was dissolved as a 80 mM stock solution in vehicle (2%

20 ethanol: 98% PEG 400, Sigma Chemical Company, St. Louis, Missouri, USA). At the start of the experiment all animals received 0.2 ml of a solution containing [ $^3\text{H}$ ] -CE-HDL into the jugular vein. [ $^3\text{H}$ ] -CE-HDL is a preparation of human HDL containing tritium-labeled cholesteryl

25 ester, and was prepared according to the method of Glenn et al. ("Quantification of Cholesteryl Ester Transfer Protein (CETP): A) CETP Activity and B) Immunochemical Assay of CETP Protein," *Meth. Enzymol.*, Glenn and Melton (Meth. Enzymol., 263, 339-351 (1996) which is

30 incorporated herein by reference).

After 2 minutes, the animals received 0.1 ml of the test solution injected into the jugular vein. Control animals received 0.1 ml of the vehicle solution without test compound. After 5 minutes, the first blood samples 35 (0.5 ml) were taken from the carotid artery and collected in standard microtainer tubes containing ethylenediamine

tetraacetic acid. Saline (0.5 ml) was injected to flush the catheter and replace blood volume. Subsequent blood samples were taken at two hours and four hours by the same method. Blood samples were mixed well and kept on ice until the completion of the experiment.

Plasma was obtained by centrifugation of the blood samples at 4° C. The plasma (50 µl) was then treated with 5 µl of precipitating reagent (dextran sulfate, 10 g/l; 0.5M magnesium chloride to remove VLDL/LDL. After centrifugation, the resulting supernatant (25 µl) containing the HDL was analyzed for radioactivity using a liquid scintillation counter. The percentage [<sup>3</sup>H]-CE transferred from HDL to LDL and VLDL (% transfer) was calculated based on the total radioactivity in equivalent serum samples before precipitation. Typically, the amount of transfer from HDL to LDL and VLDL in control animals was 30 to 35% after four hours. The polyethylene glycol vehicle was determined to have no effect on CETP activity in this model.

Table 14 shows the results of an experiment utilizing five animals that received Dimethyl 5,5'-dithiobis[2-difluoromethyl)-4-(2-methylpropyl)-6-(trifluoromethyl)-3-pyridinecarboxylate] (Compound 181), and five animals that received vehicle. At two hours, mean values of 13% [<sup>3</sup>H]-Ce transfer from HDL to LDL and VLDL were obtained for the control animals, but only 4.7% transfer for the animals receiving Compound 181. This represents a 64% inhibition of CETP activity. Student t-tests were performed to determine if the means for control and animals treated with Compound 181 were statistically different. Values of p<0.01 for both sets of data indicate that the differences are highly significant.

TABLE 14

		% Transfer		% Inhibition	
		Control	Compound 181	Compound 181	t-Test
5	Two Hours	13	4.7	63.6	0.008
	Four hours	21.6	10.6	50.8	0.001

Similarly, in separate experiments a mean of 21.6% [<sup>3</sup>H]-CE transfer was obtained for the control animals at 10 four hours, but only 10.6% was transferred in animals treated with methyl 2-(difluoromethyl)-5-mercaptop-4-(2-methylpropyl)-6-(trifluoromethyl)-3-pyridine-carboxylate (Compound 7), representing a 50% inhibition of CETP activity.

Example 57**Chronic Inhibition of CETP Activity In Vivo**

Chronic inhibition of CETP can be achieved by administration of Dimethyl 5,5'-dithiobis[2-difluoromethyl]-4-(2-methylpropyl)-6-(trifluoromethyl)-3-pyridinecarboxylate] (Compound 181) to hamsters using Alzet pump delivery of Compound 181 into the jugular veins of hamsters. Inhibition of CETP should lead to an increase in HDL cholesterol with a concomitant decrease 25 in LDL cholesterol. This can be determined by filtering serum obtained at different time intervals after initiation of inhibitor infusion and quantitating the amount of cholesterol in the LDL and HDL peaks, respectively. In addition the activity of CETP in the 30 serum can be assessed in an ex vivo CETP activity assay.

Male golden Syrian hamsters were maintained on a diet of normal rodent chow enriched with 0.24% cholesterol for at least 2 weeks prior to study. On Day 1, the hamsters were anesthetized with pentobarbital. An 35 indwelling catheter was inserted into the jugular vein and exteriorized onto the back of the neck. The hamsters

received 100 $\mu$  of Compound 181 (38.5 mg/kg) in a 2% ethanol:98% PEG400 vehicle, or the 2% ethanol:98% PEG400 vehicle alone. An Alzet pump was then attached to the jugular catheter which delivered a steady infusion of 5 24 $\mu$ l/day for a dose of 1.3 mg/day(9.2 mg/kg/day). The hamsters received the vehicle (2%ETOH:98%PEG400) or Compound 181 for 8 days. The hamsters were maintained for 10 12 days. Blood samples were taken on day 1 (pre-bleed) at the time of surgery, and on days 5, 7, 8 and 12. Fast Protein Liquid Chromatography (FPLC) on tandem Superose 6 columns of pooled hamster serum was performed to obtain cholesterol profiles for the two experimental groups.

Table 15 shows the results of an experiment 15 utilizing 5 hamsters in each group, vehicle and Compound 181. Serum cholesterol profiles were determined on pooled sera from each group. Total serum cholesterol and CETP activity were determined on individual serum samples. In hamsters administered Compound 181 20 chronically; there was a 30% reduction and 26% increase in LDL cholesterol and HDL cholesterol concentrations, respectively, compared to the vehicle group at Day 5. The decrease in LDL and increase in HDL persisted until Day 8 when the Alzet pump was exhausted. At Day 12, LDL 25 cholesterol concentrations began to rise and HDL cholesterol concentrations started to decrease toward the concentrations in the vehicle group (90% and 114% of vehicle group, respectively). It should be noted that an average 10% reduction in CETP activity was determined by 30 ex vivo assay on Days 5 and 8 with a return to vehicle control level by day 12. Therefore, it would appear that for every percent reduction in CETP activity determined by the ex vivo assay, there was a 2-3% decrease in LDL cholesterol or increase in HDL cholesterol 35 concentrations.

## INTERNATIONAL SEARCH REPORT

International application No.

PCT/US 99/01871

### Box I Observations where certain claims were found unsearchable (Continuation of item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1.  Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:
  
2.  Claims Nos.: because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:  
See FURTHER INFORMATION sheet PCT/ISA/210
  
3.  Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

### Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

1.  As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
  
2.  As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
  
3.  As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
  
  
4.  No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

#### Remark on Protest

- The additional search fees were accompanied by the applicant's protest.  
 No protest accompanied the payment of additional search fees.

FURTHER INFORMATION CONTINUED FROM PCT/ISA/ 210

Continuation of Box I.2

The present claims relate to an extremely large number of possible compounds. In fact, the claims contain so many options, variables, possible permutations and provisos that a lack of clarity and conciseness within the meaning of Article 6 PCT arises to such an extent as to render a meaningful search of the claims impossible.

Consequently, the search has been carried out for those parts of the application which do appear to be clear and concise, namely those compounds recited in the examples and closely related homologous compounds.

The applicant's attention is drawn to the fact that claims relating to inventions in respect of which no international search report has been established need not be the subject of an international preliminary examination (Rule 66.1(e) PCT). The applicant is advised that the EPO policy when acting as an International Preliminary Examining Authority is normally not to carry out a preliminary examination on matter which has not been searched. This is the case irrespective of whether or not the claims are amended following receipt of the search report or during any Chapter II procedure.
